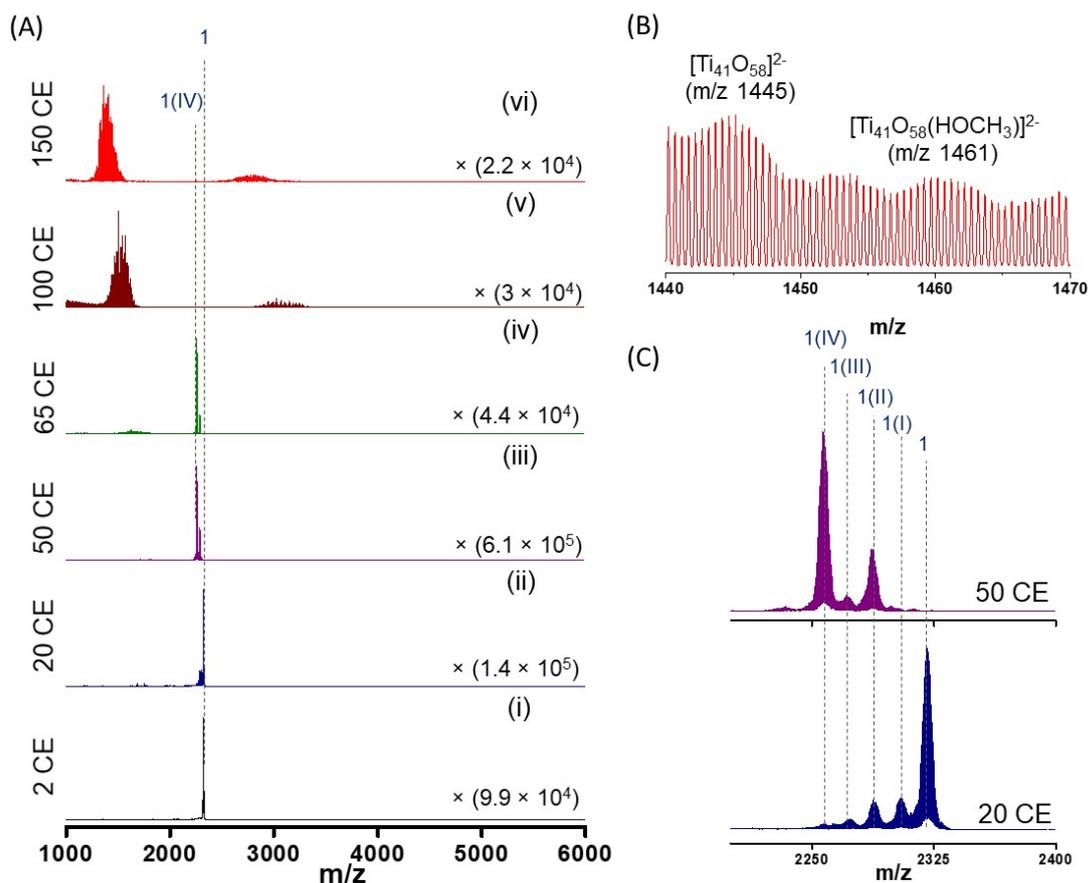

Fig. S3 Detailed CID mass spectrum of $[\text{H}_{12}\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{42}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$ (**1**) with gradual increase of collision energy. (A) MS/MS spectra from 2-150 CE. (B) shows the expanded view of the spectrum at 150 CE in the m/z range of m/z 1440-1470. Mass spectrum of $[\text{Ti}_{41}\text{O}_{58}]^{2-}$ and $[\text{Ti}_{41}\text{O}_{58}(\text{HOCH}_3)]^{2-}$ are labeled at m/z 1445 and m/z 1461 respectively. (C) shows the expanded spectra in m/z range of 2200-2400 at 20 CE and 50 CE. 1(I), 1(II), 1(III) and 1(IV) correspond to one, two, three, and four methanol loss species from the precursor ion **1**, with molecular formulae $[\text{H}_{11}\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{41}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$, $[\text{H}_{10}\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{40}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$, $[\text{H}_9\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{39}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$, $[\text{H}_8\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{38}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$, respectively.

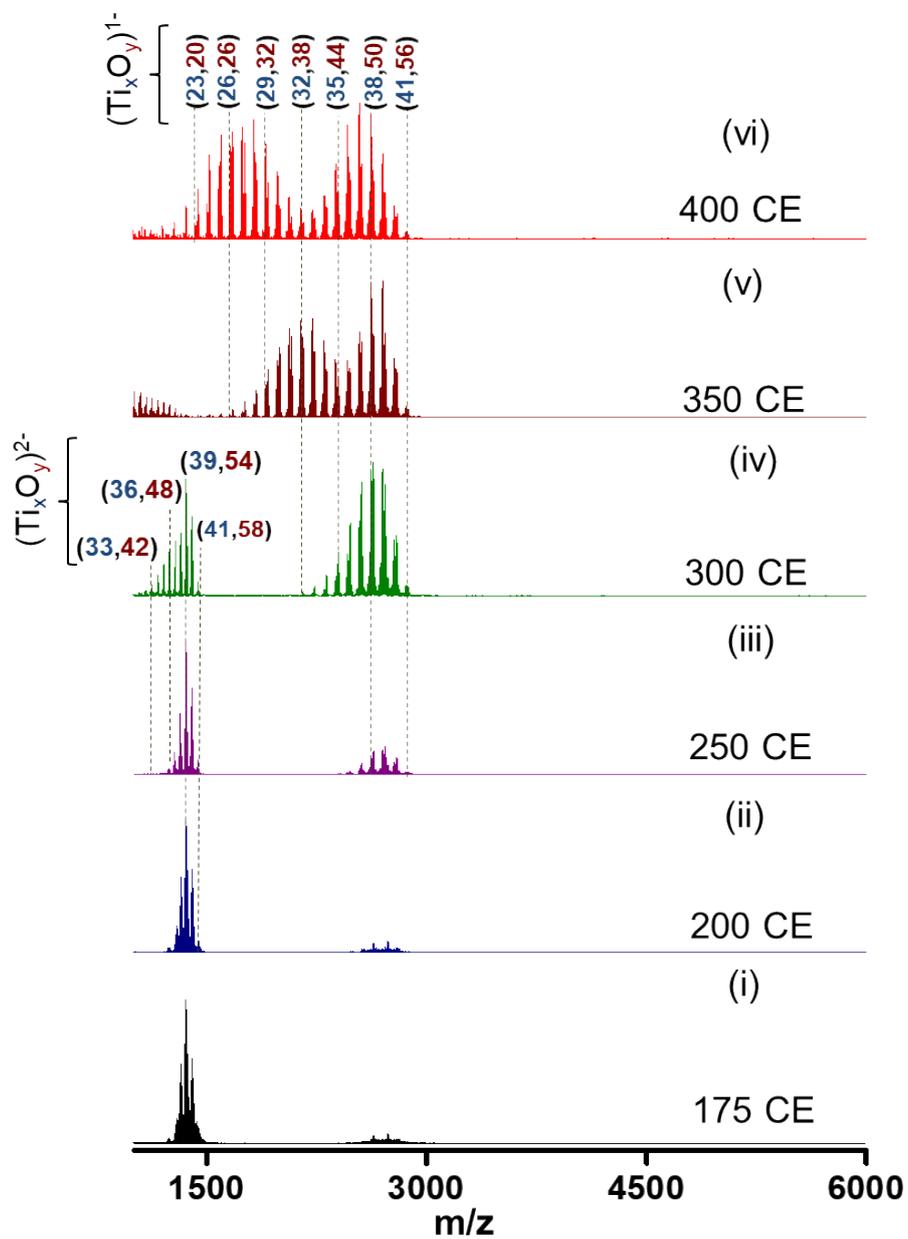

Fig. S4 Detailed CID mass spectrum of $[\text{H}_{12}\text{Ti}_{42}\text{O}_{60}(\text{OCH}_3)_{42}(\text{HOCH}_3)_{10}(\text{H}_2\text{O})_2]^{2-}$ (**1**) with the gradual increase of CE from 175- 400 CE.

4 **S11 Additional details of computational study** – DFT calculations were performed with the
 5 GPAW method. The atom PAW setups were used as Ti ($3s^24s^23p^63d^2$), O ($2s^22p^4$), C ($2s^22p^2$),
 6 and H($1s^1$) to denote the adequate valance electronic interactions in the calculations. The initial
 7 structure of **1** was optimized by taking the crystal structure of TOF, as reported by Gao et al
 8 and removing its 6Hs.¹ All geometry optimizations were carried out with a grid spacing of 0.2
 9 Å and standard force minimization conditions. PBE exchange functional and double zeta
 10 polarization (DZP) basis set were used only because these are accurate enough to give
 11 reasonably accuracy for metal cluster systems and are widely used combination in atomic-
 12 orbital DFT simulations for nanoclusters.²⁻⁴

26 **Fig. S11** Various binding modes and types of electron donation of the methoxide ligand with the Ti1
27 centre, obtained from DFT models. (i) Sigma bonding between methoxide and Ti1 centre of TOF, (ii)
28 sigma and pi electron donation from methoxide ligand to Ti1 atom which is near to methanol
29 in cluster 1 and (iii) only sigma bonding between methoxy and Ti1 centre which is near to the cage-
30 H₂O molecules.

31 **SI2 Explanation of difference in charges between protonated and unprotonated**
32 $[Ti_{42}O_{60}(MeO)_{42}(MeOH)_{10}(H_2O)_2]^{-2}$

1

2 It is likely that in the gas phase the hydrogen atoms are strongly bonded to the bridging O sites
3 on the surface of the cage, while in the crystal and solution phase the extra hydrogen atoms are
4 more loosely bound to the cluster. This being the case we may treat the twelve H atoms as
5 additional acceptor atoms to the ligands of the cluster. We know from the crystal structure of
6 TOF that there are six preferential sites octahedrally arranged for the six hydrogen atoms
7 though we do not know their exact placement and when we have twelve hydrogen atoms due
8 to symmetry considerations, they will be bonded to the bridging O atoms as six pairs of
9 hydrogen atoms at these six octahedral sites with each H atom donating $1e$.

10 We verified that the single-electron donation of H to Ti indeed yields the overall cluster -2
11 charge according to the standard textbook rules for calculating the charges of organometallic
12 complexes and we only assumed that the two water molecules and ten methanol molecules
13 inside the cage do not donate electrons to Ti. Assuming an oxidation state of 4 for Ti the number
14 of charges on Ti atoms is $42 \times 4e = 168e$. Twelve H atoms are in +1 oxidation state, so electrons
15 accepted by Hs are $12 \times 1e = 12e$. The charges donated by ligands are as following the 10 -OMe
16 ligands (connected to Ti1, close to MeOH) ($10 \times 3e = 30e$), 2 -OMe ligands (connected to Ti1,
17 close to H₂O) $2 \times 1e = 2e$. Remaining 30 -OMe (Ti2 site) ligands and 60 μ_3 -bridging atoms
18 donate $(30 \times 1e) = 30e$, $(60 \times 2e) = 120e$ respectively to the Ti atoms. Therefore, total charges
19 donated by ligands is $(30+2+30+120)e = 182e$ to Ti. Therefore, the charge on the cluster is
20 $168+12-182 = -2$.
